

Announcing a New Implementation of

T
A DIALECT OF SCHEME

Implemented by

Norman Adams	Richard Kelsey	David Kranz
James Philbin	Kent Pitman	Jonathan Rees

T *version 3* is a superset of Scheme. T's extensions to Scheme include: multiple return values, object oriented programming, first class environments, an extensive macro system, dynamic binding, tables, populations, pools, a debugger and inspector, and weak pointers. The system contains an environment that conforms to the *Revised³ Report on Scheme*.

The new system includes both an interpreter and a highly optimizing native code compiler, which compiles closures efficiently. The compiler produces code that is competitive with the best Lisp, C, and Pascal compilers. The system and compiler are written almost entirely in T.

T is intended for use in education, systems programming, AI programming, and for programming language design and development.

T is distributed at cost without license. The copyright is held by Yale University. Users can copy and redistribute the software subject to certain restrictions. The current distribution cost is \$200 inside the continental USA and \$250 outside. The distribution includes both binaries and sources. Availability is as follows:

Apollo	September 1986
HP9000/300	September 1986
Sun (II & III)	September 1986
Vax Unix BSD	September 1986
VMS	October 1986
